### ^ Abstract

We investigated the cellular mechanisms of the unique disorder of insulin action found in the polycystic ovary syndrome (PCOS). Approximately 50% of PCOS women (PCOS-Ser) had a significant increase in insulin-independent beta-subunit [32P]phosphate incorporation (3.7-fold,  $P < 0.05$  vs other groups) in skin fibroblast insulin receptors that was present in serine residues while insulin-induced tyrosine phosphorylation was decreased (both  $P < 0.05$  vs other groups). PCOS skeletal muscle insulin receptors had the same abnormal phosphorylation pattern. The remaining PCOS women (PCOS-n1) had basal and insulin-stimulated receptor autophosphorylation similar to control. Phosphorylation of the artificial substrate poly GLU4:TYR1 by the PCOS-Ser insulin receptors was significantly decreased ( $P < 0.05$ ) compared to control and PCOS-n1 receptors. The factor responsible for excessive serine phosphorylation appeared to be extrinsic to the receptor since no insulin receptor gene mutations were identified, immunoprecipitation before autophosphorylation corrected the phosphorylation defect and control insulin receptors mixed with lectin eluates from affected PCOS fibroblasts displayed increased serine phosphorylation. Our findings suggest that increased insulin receptor serine phosphorylation decreases its protein tyrosine kinase activity and is one mechanism for the post-binding defect in insulin action characteristic of PCOS.

**Abstract**

**Background:** The aim of this study was to evaluate the effect of the use of a mobile phone on the performance of a simulated driving task.

**Methods:** A total of 20 participants were recruited and divided into two groups: a control group and an experimental group. The control group was asked to perform a simulated driving task without the use of a mobile phone, while the experimental group was asked to perform the same task while using a mobile phone. The performance of both groups was compared in terms of reaction time, error rate, and subjective workload.

**Results:** The results showed that the use of a mobile phone significantly increased the reaction time and error rate of the participants in the experimental group compared to the control group. Additionally, the subjective workload was significantly higher in the experimental group.

**Conclusion:** The use of a mobile phone during a simulated driving task significantly impairs performance, as evidenced by increased reaction time, error rate, and subjective workload.

Insulin resistance and the polycystic ovary syndrome revisited: an update on mechanisms and implications. *Endocr Rev* 2012; 33:981. Barbieri RL, Smith S, Ryan KJ. Polycystic ovary syndrome (PCOS) is characterized by hyperandrogenemia that is amplified by insulin in the presence of resistance to insulin's action to stimulate glucose uptake in muscle and fat. To explore the mechanisms for this paradox, we examined the metabolic and mitogenic actions of insulin and insulin-like growth factor I (IGF-I) in cultured skin fibroblasts from PCOS (n = 16) and control (n = 11) women. There were no significant decreases in the number or affinity of insulin- or IGF-I... CONTINUE READING. [View on PubMed.](#)
