Abstract

The CoNLL-2014 shared task was devoted to grammatical error correction of all error types. In this paper, we give the task definition, present the data sets, and describe the evaluation metric and scorer used in the shared task. We also give an overview of the various approaches adopted by the participating teams, and present the evaluation results. Compared to the CoNLL-2013 shared task, we have introduced the following changes in CoNLL-2014: (1) A participating system is expected to detect and correct grammatical errors of all types, instead of just the five error types in CoNLL-2013; (2) The evaluation metric was changed from $F_1$ to $F_{0.5}$, to emphasize precision over recall; and (3) We have two human annotators who independently annotated the test essays, compared to just one human annotator in CoNLL-2013.

1 Introduction

Grammatical error correction is the shared task of the Eighteenth Conference on Computational Natural Language Learning in 2014 (CoNLL-2014). In this task, given an English essay written by a learner of English as a second language, the goal is to detect and correct the grammatical errors of all error types present in the essay, and return the corrected essay.

This task has attracted much recent research interest, with two shared tasks Helping Our Own (HOO) organized in 2011 and 2012 (Dale and Kilgarriff, 2011; Dale et al., 2012), and a CoNLL shared task on grammatical error correction organized in 2013 (Ng et al., 2013). In contrast to previous CoNLL shared tasks which focused on particular subtasks of natural language processing, such as named entity recognition, semantic role labeling, dependency parsing, or coreference resolution, grammatical error correction aims at building a complete end-to-end application. This task is challenging since for many error types, current grammatical error correction systems do not achieve high performance and much research is still needed. Also, tackling this task has far-reaching impact, since it is estimated that hundreds of millions of people worldwide are learning English and they benefit directly from an automated grammar checker.

The CoNLL-2014 shared task provides a forum for participating teams to work on the same grammatical error correction task, with evaluation on the same blind test set using the same evaluation metric and scorer. This overview paper contains a detailed description of the shared task, and is organized as follows. Section 2 provides the task definition. Section 3 describes the annotated training data provided and the blind test data. Section 4 describes the evaluation metric and the scorer. Section 5 lists the participating teams and outlines the approaches to grammatical error correction used by the teams. Section 6 presents the results of the shared task, including a discussion on cross annotator comparison. Section 7 concludes the paper.

2 Task Definition

The goal of the CoNLL-2014 shared task is to evaluate algorithms and systems for automatically detecting and correcting grammatical errors
present in English essays written by second language learners of English. Each participating team is given training data manually annotated with corrections of grammatical errors. The test data consists of new, blind test essays. Preprocessed test essays, which have been sentence-segmented and tokenized, are also made available to the participating teams. Each team is to submit its system output consisting of the automatically corrected essays, in sentence-segmented and tokenized form.

Grammatical errors consist of many different types, including articles or determiners, prepositions, noun form, verb form, subject-verb agreement, pronouns, word choice, sentence structure, punctuation, capitalization, etc. However, most prior published research on grammatical error correction only focuses on a small number of frequently occurring error types, such as article and preposition errors (Han et al., 2006; Gamon, 2010; Rozovskaya and Roth, 2010; Tetreault et al., 2010; Dahlmeier and Ng, 2011b). Article and preposition errors were also the only error types featured in the HOO 2012 shared task. Likewise, although all error types were included in the HOO 2011 shared task, almost all participating teams dealt with article and preposition errors only (besides spelling and punctuation errors). In the CoNLL-2013 shared task, the error types were extended to include five error types, comprising article or determinant, preposition, noun number, verb form, and subject-verb agreement. Other error types such as word choice errors (Dahlmeier and Ng, 2011a) were not dealt with.

In the CoNLL-2014 shared task, it was felt that the community is now ready to deal with all error types. Table 1 shows examples of the 28 error types in the CoNLL-2014 shared task.

Since there are 28 error types in our shared task compared to two in HOO 2012 and five in CoNLL-2013, there is a greater chance of encountering multiple, interacting errors in a sentence in our shared task. This increases the complexity of our shared task. To illustrate, consider the following sentence:

Social network plays a role in providing and also filtering information.

The noun number error networks needs to be corrected (network → networks). This necessitates the correction of a subject-verb agreement error (plays → play). A pipeline system in which corrections for subject-verb agreement errors occur strictly before corrections for noun number errors would not be able to arrive at a fully corrected sentence for this example. The ability to correct multiple, interacting errors is thus necessary in our shared task. The recent work of Dahlmeier and Ng (2012a) and Wu and Ng (2013), for example, is designed to deal with multiple, interacting errors.

3 Data

This section describes the training and test data released to each participating team in our shared task.

3.1 Training Data

The training data provided in our shared task is the NUCLE corpus, the NUS Corpus of Learner English (Dahlmeier et al., 2013). As noted by (Leacock et al., 2010), the lack of a manually annotated and corrected corpus of English learner texts has been an impediment to progress in grammatical error correction, since it prevents comparative evaluations on a common benchmark test data set. NUCLE was created precisely to fill this void. It is a collection of 1,414 essays written by students at the National University of Singapore (NUS) who are non-native speakers of English. The essays were written in response to some prompts, and they cover a wide range of topics, such as environmental pollution, health care, etc. The grammatical errors in these essays have been hand-corrected by professional English instructors at NUS. For each grammatical error instance, the start and end character offsets of the erroneous text span are marked, and the error type and the correction string are provided. Manual annotation is carried out using a graphical user interface specifically built for this purpose. The error annotations are saved as stand-off annotations, in SGML format.

To illustrate, consider the following sentence at the start of the sixth paragraph of an essay:

Nothing is absolute right or wrong.

There is a word form error (absolute → absolutely) in this sentence. The error annotation, also called correction or edit, in SGML format is shown in Figure 1. start_par (end_par) denotes the paragraph ID of the start (end) of the erroneous
Table 1: The 28 error types in the shared task.

text span (paragraph ID starts from 0 by convention). start_off (end_off) denotes the character offset of the start (end) of the erroneous text span (again, character offset starts from 0 by convention). The error tag is Wform, and the correction string is absolutely.

The NUCLE corpus was first used in (Dahlmeier and Ng, 2011b), and has been publicly available for research purposes since June 2011

1

http://www.comp.nus.edu.sg/~nlp/corpora.html

1

All instances of grammatical errors are annotated in NUCLE.

To help participating teams in their preparation for the shared task, we also performed automatic preprocessing of the NUCLE corpus and released the preprocessed form of NUCLE. The preprocessing operations performed on the NUCLE essays include sentence segmentation and word tokenization using the NLTK toolkit (Bird et al., 2009), and part-of-speech (POS) tagging, constituency and dependency tree parsing using the Stanford parser (Klein and Manning, 2003; de Marneffe et al., 2006). The error annotations, which are originally at the character level, are then mapped to error annotations at the word token level. Error annotations at the word token level also facilitate scoring, as we will see in Section 4, since our scorer operates by matching tokens. Note that although we released our own preprocessed version of NUCLE, the participating teams were however free to perform their own preprocessing if they so preferred.

NUCLE release version 3.2 was used in the CoNLL-2014 shared task. In this version, 17 essays were removed from the first release of NUCLE since these essays were duplicates with multiple annotations. In addition, in order to facilitate the detection and correction of article/determiner errors and preposition errors, we performed some automatic mapping of error types in the original NUCLE corpus to arrive at release version 3.2. Ng et al. (2013) gives more details of how the mapping was carried out.

The statistics of the NUCLE corpus (release 3.2 version) are shown in Table 2. The distribution of errors among all error types is shown in Table 3.

While the NUCLE corpus is provided in our shared task, participating teams are free to not use NUCLE, or to use additional resources and tools in building their grammatical error correction systems, as long as these resources and tools are publicly available and not proprietary. For example, participating teams are free to use the Cambridge FCE corpus (Yannakoudakis et al., 2011; Nicholls, 2003) (the training data provided in HOO 2012 (Dale et al., 2012)) as additional training data.

3.2 Test Data

Similar to CoNLL-2013, 25 NUS students, who are non-native speakers of English, were recruited to write new essays to be used as blind test data in the shared task. Each student wrote two essays in response to the two prompts shown in Table 4, one essay per prompt. The first prompt was also used in the NUCLE training data, but the second prompt is entirely new and not used previously. As a result, 50 new test essays were collected. The statistics of the test essays are also shown in Table 2.

Error annotation on the test essays was carried out independently by two native speakers of English. One of them is a lecturer at the NUS Centre for English Language Communication, and the other is a freelance English linguist with extensive prior experience in error annotation of English learners’ essays. The distribution of errors in the test essays among the error types is shown in Table 3. The test essays were then preprocessed in the same manner as the NUCLE corpus. The preprocessed test essays were released to the participating teams. Similar to CoNLL-2013, the test essays and their error annotations in the CoNLL-2014 shared task will be made freely available after the shared task.

4 Evaluation Metric and Scorer

A grammatical error correction system is evaluated by how well its proposed corrections or edits match the gold-standard edits. An essay is first sentence-segmented and tokenized before evaluation is carried out on the essay. To illustrate, consider the following tokenized sentence $S$ written by an English learner:

<table>

</table>

Table 3: Error type distribution of the training and test data. The test data were annotated independently by two annotators.
There is no **doubt**, tracking **system** has brought many benefits in this information age.

The set of gold-standard edits of a human annotator is $g = \{\text{a doubt} \rightarrow \text{doubt}, \text{system} \rightarrow \text{systems}, \text{has} \rightarrow \text{have}\}$. Suppose the tokenized output sentence $H$ of a grammatical error correction system given the above sentence is:

There is no doubt, tracking system has brought many benefits in this information age.

That is, the set of system edits is $e = \{\text{a doubt} \rightarrow \text{doubt}\}$. The performance of the grammatical error correction system is measured by how well the two sets $g$ and $e$ match, in the form of recall $R$, precision $P$, and $F_{0.5}$ measure: $R = 1/3, P = 1/1, F_{0.5} = (1 + 0.5^2) \times RP/(R + 0.5^2 \times P) = 5/7$.

More generally, given a set of $n$ sentences, where $g_i$ is the set of gold-standard edits for sentence $i$, and $e_i$ is the set of system edits for sentence $i$, recall, precision, and $F_{0.5}$ are defined as follows:

$$R = \frac{\sum_{i=1}^{n} |g_i \cap e_i|}{\sum_{i=1}^{n} |g_i|} \quad (1)$$

$$P = \frac{\sum_{i=1}^{n} |g_i \cap e_i|}{\sum_{i=1}^{n} |e_i|} \quad (2)$$

$$F_{0.5} = \frac{(1 + 0.5^2) \times R \times P}{R + 0.5^2 \times P} \quad (3)$$

where the intersection between $g_i$ and $e_i$ for sentence $i$ is defined as

$$g_i \cap e_i = \{e \in e_i | \exists g \in g_i, \text{match}(g, e)\} \quad (4)$$

Note that we have adopted $F_{0.5}$ as the evaluation metric in the CoNLL-2014 shared task instead of the standard $F_1$ used in CoNLL-2013. $F_{0.5}$ emphasizes precision twice as much as recall, while $F_1$ weighs precision and recall equally. When a grammar checker is put into actual use, it is important that its proposed corrections are highly accurate in order to gain user acceptance. Neglecting to propose a correction is not as bad as proposing an erroneous correction.

Similar to CoNLL-2013, we use the MaxMatch (M$^2$) scorer\(^2\) (Dahlmeier and Ng, 2012b) as the official scorer in CoNLL-2014. The M$^2$ scorer\(^3\) efficiently searches for a set of system edits that maximally matches the set of gold-standard edits specified by an annotator. It overcomes a limitation of the scorer used in HOO shared tasks, which can return an erroneous score since the system edits are computed deterministically by the HOO scorer without regard to the gold-standard edits.

### 5 Approaches

45 teams registered to participate in the shared task, out of which 13 teams submitted the output of their grammatical error correction systems. These teams are listed in Table 5. Each team is assigned a 3 to 4-letter team ID. In the remainder of this paper, we will use the assigned team ID to refer to a participating team. Every team submitted a system description paper (the only exception is the NARA team). Four of the 13 teams submitted their system output only after the deadline (they were given up to one week of extension). These four teams (IIITB, IPN, PKU, and UFC) have an asterisk affixed after their team names in Table 5.

Each participating team in the CoNLL-2014 shared task tackled the error correction problem in a different way. A full list summarizing each

team’s approach can be found in Table 6. While machine-learnt classifiers for specific error types proved popular in last year’s CoNLL-2013 shared task, since this year’s task required the correction of all 28 error types, teams tended to prefer methods that could deal with all error types simultaneously. In fact, most teams built hybrid systems that made use of a combination of different approaches to identify and correct errors.

One of the most popular approaches to non-specific error type correction, incorporated to various extents in many teams’ systems, was the Language Model (LM) based approach. Specifically, the probability of a learner n-gram is compared with the probability of a candidate corrected n-gram, and if the difference is greater than some threshold, an error was perceived to have been detected and a higher scoring replacement n-gram could be suggested. Some teams used this approach only to detect errors, e.g., IPN (Hernandez and Calvo, 2014), which could then be corrected by other methods, whilst other teams used other methods to detect errors first, and then made corrections based on the alternative highest n-gram probability score, e.g., RAC (Boroș et al., 2014).

MT approach mainly differed in terms of their attitude toward tuning; CAMB (Felice et al., 2014) performed no tuning at all, IITB (Kunchukuttan et al., 2014) and UMC (Wang et al., 2014b) tuned $F_{0.5}$ using MERT, while AMU (Junczys-Dowmunt and Grundkiewicz, 2014) explored a variety of tuning options, ultimately tuning $F_{0.5}$ using a combination of kb-MIRA and MERT. No team used a syntax-based translation model, although UMC did include POS tags and morphology in a factored translation model.

With regard to correcting single error types, rule-based (RB) approaches were also common in most teams’ systems. A possible reason for this is that some error types are more regular than others, and so in order to boost accuracy, simple rules can be written to make sure that, for example, the number of a subject agrees with the number of a verb. In contrast, it is a lot harder to write a rule to consistently correct Wci (wrong collocation/idiom) errors. As such, RB methods were often, but not always, used as a preliminary or supplementary stage in a larger hybrid system.

Finally, although there were fewer machine-learnt classifier (ML) approaches than last year, some teams still used various classifiers to correct specific error types. In fact, CUUI (Rozovskaya et al., 2014) only built classifiers for specific error types and did not attempt to tackle the whole range of errors. SJTU (Wang et al., 2014a) also preprocessed the training data into more precise error categories using rules (e.g., verb tense (Vt))
errors might be subcategorized into present, past, or future tense etc.) and then built a single maximum entropy classifier to correct all error types. See Table 6 to find out which teams tackled which error types.

While every effort has been made to make clear which team used which approach to correct which set of error types, as there were more error types than last year, it was sometimes impractical to fit all this information into Table 6. For more information on the specific methods used to correct a specific error type, we must refer the reader to that team’s CoNLL-2014 system description paper.

Table 6 also shows the linguistic features used by the participating teams, which include lexical features (i.e., words, collocations, n-grams), parts-of-speech (POS), constituency parses, and dependency parses.

While all teams in the shared task used the NUCLE corpus, they were also allowed to use additional external resources (both corpora and tools) so long as they were publicly available and not proprietary. Three teams also used last year’s CoNLL-2013 test set as a development set in this year’s CoNLL-2014 shared task. The external resources used by the teams are also listed in Table 6.

6 Results

All submitted system output was evaluated using the M² scorer, based on the error annotations provided by our annotators. The recall (R), precision (P), and $F_{0.5}$ measure of all teams are shown in Table 7. The performance of the teams varies greatly, from little more than five per cent to 37.33% for the top team.

The nature of grammatical error correction is such that multiple, different corrections are often acceptable. In order to allow the participating teams to raise their disagreement with the original gold-standard annotations provided by the annotators, and not underestimate the performance of the teams, we allow the teams to submit their proposed alternative answers. This was also the practice adopted in HOO 2011, HOO 2012, and CoNLL-2013. Specifically, after the teams submitted their system output and the error annotations on the test essays were released, we allowed the teams to propose alternative answers (gold-standard edits), to be submitted within four days after the initial error annotations were released.

The same annotators who provided the error annotations on the test essays also judged the alternative answers proposed by the teams, to ensure consistency. In all, three teams (CAMB, CUUI, UMC) submitted alternative answers.

The same submitted system output was then evaluated using the M² scorer, with the original annotations augmented with the alternative answers. Table 8 shows the recall (R), precision (P), and $F_{0.5}$ measure of all teams under this new evaluation setting.

The $F_{0.5}$ measure of every team improves when evaluated with alternative answers. Not surprisingly, the teams which submitted alternative answers tend to show the greatest improvements in their $F_{0.5}$ measure. Overall, the CUUI team (Rozovskaya et al., 2014) achieves the best $F_{0.5}$ measure when evaluated with alternative answers, and the CAMB team (Felice et al., 2014) achieves the best $F_{0.5}$ measure when evaluated without alternative answers.

For future research which uses the test data of the CoNLL-2014 shared task, we recommend that evaluation be carried out in the setting that does not use alternative answers, to ensure a fairer evaluation. This is because the scores of the teams which submitted alternative answers tend to be higher in a biased way when evaluated with alternative answers.

We are also interested in the analysis of the system performance for each of the error types.

Table 6: Profile of the participating teams. The Error column lists the error types tackled by a team if not all were corrected. The Approach column lists the type of approach used, where LM denotes a Language Modeling based approach, ML a Machine Learning classifier based approach, MT a statistical Machine Translation approach, and RB a Rule-Based approach.

**Footnote:** The RAC team uses rules to correct errors that differ from the 28 official error types. They include: “the correction of the verb tense especially in time clauses, the use of the short infinitive after modals, the position of frequency adverbs in a sentence, subject-verb agreement, word order in interrogative sentences, punctuation accompanying certain lexical elements, the use of articles, etc.”

Computing the recall of an error type is straightforward as the error type of each gold-standard edit is provided. Conversely, computing the precision of each of the 28 error types is difficult as the error type of each system edit is not available since the submitted system output only contains corrected sentences with no indication of the error type of the system edits. Predicting the error type out of the 28 types for a particular system edit not found in gold-standard annotation can be tricky and error-prone. Therefore, we decided to compute the per-type performance based on recall. The recall scores when distinguished by error type are shown in Tables 9 and 10.

#### 6.1 Cross Annotator Comparison

To measure the agreement between our two annotators, we computed Cohen’s Kappa coefficient (Cohen, 1960) for identification, which measures the extent to which annotators agreed which words needed correction and which did not, regardless of the error type or correction. We obtained a Kappa coefficient value of 0.43, indicating moderate agreement (since it falls between 0.40 and 0.60). While this may seem low, it is worth pointing out that the Kappa coefficient does not take into account the fact that there is often more than one valid way to correct a sentence.

In addition to computing the performance of each team against the gold standard annotations of both annotators with and without alternative annotations, we also had an opportunity to compare the performance of each team’s system against each annotator individually.

A recent concern is that there can be a high degree of variability between individual annotators which can dramatically affect a system’s output score. For example, in a much simplified error correction task concerning only the correction of prepositions, Tetreault and Chodorow (2008) showed an actual difference of 10% precision and 5% recall between two annotators. Table 11 hence shows the precision \((P)\), recall \((R)\), and \(F_{0.5}\) scores for all error types against the gold standard annotations of each CoNLL-2014 annotator individually.

The results show that there can indeed be a high amount of disagreement between two annotators, the most noticeable being precision in the UFC system: precision was 70% for Annotator 2 but only 28% for Annotator 1. This 42% difference is, however, likely to be an extreme case, and most teams show little more than 10% variation in precision and 5% variation in \(F_{0.5}\). Recall remained fairly constant between annotators. 10% is still a large margin however, and these results reinforce the idea that error correction systems should be judged against the gold-standard annotations of multiple annotators.

Table 12 additionally shows how each annotator compares against each other; i.e., what score Annotator 1 gets if Annotator 2 was the gold standard (part (a) of Table 12) and vice versa (part (b)).

The low \(F_{0.5}\) scores of 45.36% and 38.54% represent an upper bound for system performance on this data set and again emphasize the difficulty of the task. The low human \(F_{0.5}\) scores imply that there are many ways to correct a sentence.

#### 7 Conclusions

The CoNLL-2014 shared task saw the participation of 13 teams worldwide to evaluate their grammatical error correction systems on a common test set, using a common evaluation metric and scorer. The best systems in the shared task achieve an \(F_{0.5}\) score of 37.33% when it is scored without alternative answers, and 45.57% with alternative answers. There is still much room for improvement in the accuracy of grammatical error correction systems. The evaluation data sets and scorer used in our shared task serve as a benchmark for

Table 12: Performance (in %) for output of one gold standard annotation scored against the other gold standard annotation: (a) The score of Annotator 1 if Annotator 2 was the gold standard, (b) The score of Annotator 2 if Annotator 1 was the gold standard.

future research on grammatical error correction.

Acknowledgments

This research is supported by the Singapore National Research Foundation under its International Research Centre @ Singapore Funding Initiative and administered by the IDM Programme Office. We thank our two annotators Mark Brooke and Diane Nicholls who provided the gold-standard annotations.
